Outline: Estimation Methods

- 1. Input prices as IVs
- 2. Fixed Effects estimator
- 3. Fixed Effects + Cochrane–Orcutt estimator
- 4. Arellano-Bond estimator
- 5. Panel Data: System estimator
- 6. Control Function: Olley-Pakes estimator
- 7. Control Function: Levinsohn-Petrin estimator
- 8. Using First Order Conditions

1. Input Prices as Instruments (an IV estimator)

Victor Aguirregabiria ()

Production Functions

February 1st, 2021 3 / 62

Input prices as IVs

- If input prices r_{it} are observable (wages, cost of capital, fuel and energy prices), then under the assumption that they are not correlated with TFP, $E(\omega_{it} r_{it}) = 0$, we can use them as instruments.
- This approach has several limitations/problems.
- **Problem (1)**. Firms in the same industry typically use very similar type of inputs (labor, capital equipment, energy, materials) and they buy these inputs in the same input markets. If these input markets are competitive, the input prices are the same for all the firms in the industry:

$$r_{it} = r_t$$
 for every firm *i*

• If input prices vary only over time, they are perfectly collinear with time-dummies in the PF. No valid instruments.

▲□▶ ▲□▶ ▲□▶ ▲□▶ □ のの⊙

(2)

Input prices as IVs

- **Problem (2)**. When input prices have cross-sectional variation, it could be because endogenous reasons.
- (a) Inputs markets are not competitive and firms with higher productivity pay higher prices. Then, $cov(\omega_{it}, r_{it}) \neq 0$, making input prices not a valid instrument.
- (b) Firms may be using different types of labor or capital inputs, with different qualities. This difference in the quality of inputs is part of the log-TFP. Then, $cov(\omega_{it}, r_{it}) \neq 0$, making input prices not a valid instrument.

▲□▶ ▲□▶ ▲□▶ ▲□▶ □ のの⊙

Input prices as IVs

(3)

- An ideal situation for using input prices as IVs is when firms in the same industry product in different geographic markets where the input markets are competitive.
- The variation in input prices over geographic market is due to different conditions on the supply of inputs (e.g., labor supply, better access to materials) and not to differences in productivity.

2. Fixed Effects estimator (a CF estimator)

Victor Aguirregabiria ()

3

< ロ > < 同 > < 回 > < 回 > < 回 > < 回

Fixed-Effects (FE) estimator

• Consider the PF:

$$y_{it} = \alpha_L \ \ell_{it} + \alpha_K \ k_{it} + \omega_{it} \tag{1}$$

- Let's first define the FE (or Within-Groups) estimator and then we will show under which conditions this estimator provides unbiased (consistent) estimates of parameters α_L and α_K .
- If, for each firm *i*, we average equation (1) considering all the years observations, we have the equation:

$$\bar{y}_i = \alpha_L \ \bar{\ell}_i + \alpha_K \ \bar{k}_i + \bar{\omega}_i \tag{2}$$

where:

$$\bar{y}_i = \frac{\sum_{t=1}^T y_{it}}{T}; \ \bar{\ell}_i = \frac{\sum_{t=1}^T \ell_{it}}{T}; \ \bar{k}_i = \frac{\sum_{t=1}^T k_{it}}{T}; \ \bar{\omega}_i = \frac{\sum_{t=1}^T \omega_{it}}{T}$$

FE estimator (2)

• If we subtract equation (2) to equation (1), we have:

$$(y_{it} - \bar{y}_i) = \alpha_L \left(\ell_{it} - \bar{\ell}_i \right) + \alpha_K \left(k_{it} - \bar{k}_i \right) + (\omega_{it} - \overline{\omega}_i)$$
(3)

- This equation is named the Fixed-Effects (or the Within-Groups) transformation of the model.
- The FE estimator is OLS applied to FE transformed model.
- For instance, if we had only one input, say labor, the FE estimator of *α*_L would be:

$$\widehat{\alpha_{L}^{OLS}} = \frac{\sum_{i=1}^{N} \sum_{t=1}^{T} (y_{it} - \overline{y}_{i}) \quad \left(\ell_{it} - \overline{\ell}_{i}\right)}{\sum_{i=1}^{N} \sum_{t=1}^{T} \left(\ell_{it} - \overline{\ell}_{i}\right)^{2}}$$

(日) (同) (三) (三)

FE estimator in Stata: Implementation 1

- Let logy, logn, logk, id, year, be the variables.
- First, we construct the within-group transformation of the variables:

```
egen mlogy = mean(logy), by(id)
gen wlogy = logy - mlogy
```

```
egen mlogn = mean(logn), by(id)
gen wlogn = logn - mlogn
```

```
egen mlogk = mean(logk), by(id)
gen wlogn = logn - mlogn
```

Implementation 1

Then, run OLS using within-groups transformed variables.

reg wlogy wlogn wlogk

/ictor Aguirregabiria ()	Production F	unctions		February 1st, 2	021 13 / 62

• The FE estimator is OLS in the regression equation

$$(y_{it} - \bar{y}_i) = \alpha_L \left(\ell_{it} - \bar{\ell}_i \right) + \alpha_K \left(k_{it} - \bar{k}_i \right) + (\omega_{it} - \overline{\omega}_i)$$
(3)

• As any OLS estimator, it is consistent if the error term is not correlated with the regressors. In this case, this implies:

$$\mathbb{E}\left[\left(\omega_{it}-\overline{\omega}_{i}\right) \ \left(\ell_{it}-\overline{\ell}_{i}\right)\right] = \mathbb{E}\left[\left(\omega_{it}-\overline{\omega}_{i}\right) \ \left(k_{it}-\overline{k}_{i}\right)\right] = 0$$

• We now present two **assumptions** on the unobserved log-TFP that imply consistency of the FE estimator (with time dummies).

14 / 62

(2)

• Assumption FE-1. Log-TFP has the following structure:

$$\omega_{it} = \eta_i + \delta_t + u_{it}$$

- η_i is interpreted as managerial ability, or a different technology that is constant over time.
- δ_t represents productivity that affect in the same way to all the firms in the industry.
- *u_{it}* is a firm-specific transitory shock.

• Assumption FE-2. The firm-specific transitory shock, u_{it} , is not correlated over time and it is realized after the firm chooses the amount of inputs at period *t*.

(3)

• u_{it} is a "surprised" that is realized after the firm has chosen inputs. For any two periods t and s, u_{it} is not correlated with inputs ℓ_{is} and k_{is} .

• Under assumptions FE-1 we have that:

$$\overline{\omega}_i = \eta_i + \overline{\delta} + \overline{u}_i$$

(4)

such that:

$$\omega_{it}-\overline{\omega}_i=\delta_t-\overline{\delta}+u_{it}-\overline{u}_i$$

- If we control for $\delta_t \overline{\delta}$ using time dummies, the remaining error term is $u_{it} \overline{u}_i$.
- Under Assumption FE-2, the error term $u_{it} \overline{u}_i$ is not correlated with the regressors $(\ell_{it} \overline{\ell}_i)$ and $(k_{it} \overline{k}_i)$ because, for any two periods t and s, u_{it} is not correlated with inputs ℓ_{is} and k_{is} .
- Under FE-1 and FE-2, the FE estimator is unbiased / consistent.

3. **Fixed Effects +** Cochrane–Orcutt estimator (a CF estimator)

Victor Aguirregabiria ()

Production Functions

E 6 4 E 6 February 1st, 2021 18 / 62

- **4 A b**

3

Cochrane–Orcutt estimator

- The assumption that the firm-specific transitory shock is not serially correlated (and fully unknown to the firm at period t) is quite strong.
- This assumption is testable (Arellano-Bond test for serial correlation). If rejected, this assumption can be relaxed.
- Suppose that we maintain assumption FE-1 but we replace assumption FE-2 with the following.
- Assumption FE-CO. The firm-specific transitory shock, u_{it}, follows an Autorregressive-1 process, AR(1):

$$u_{it} = \rho \ u_{i,t-1} + a_{it}$$

where ρ is a parameter, and a_{it} is not correlated over time and it is realized after the firm chooses the amount of inputs at period t.

イロト 不得下 イヨト イヨト 二日

Cochrane–Orcutt estimator

(2)

- In this model where u_{it} is serially correlated, the standard FE estimator is inconsistent (biased) because $u_{it} \overline{u}_i$ is correlated with the regressors.
- However, we can define a new version of the FE estimator (Cochrane-Orcutt FE) that is consistent under these conditions and the additional condition that the number of periods T is large.

Cochrane–Orcutt estimator (3)

• Consider the PF at periods t and t - 1 under assumption FE-1:

$$y_{it} = \alpha_L \ell_{it} + \alpha_K k_{it} + \eta_i + \delta_t + u_{it}$$

$$y_{it-1} = \alpha_L \ell_{it-1} + \alpha_K k_{it-1} + \eta_i + \delta_{t-1} + u_{it-1}$$

• Multiplying the equation at t-1 by ρ and subtracting it to the equation at period t, we get:

$$y_{it} - \rho \ y_{it-1} = \alpha_L \left[\ell_{it} - \rho \ \ell_{it-1} \right] + \alpha_K \left[k_{it} - \rho \ k_{it-1} \right] \\ + \left[1 - \rho \right] \eta_i + \left[\delta_t - \rho \ \delta_{t-1} \right] + a_{it}$$

because $u_{it} - \rho \ u_{it-1} = a_{it}$.

• This is called a quasi-difference transformation.

Victor Aguirregabiria ()

Cochrane–Orcutt estimator (4)

• The quasi-difference transformation can be written as:

$$\begin{array}{rcl} y_{it} & = & \beta_1 \ y_{i,t-1} + \beta_2 \ \ell_{it} + \beta_3 \ \ell_{it-1} + \beta_4 \ k_{it} + \beta_5 \ k_{it-1} \\ & + & \eta_i^* + \delta_t^* + a_{it} \end{array}$$

with
$$\beta_1 = \rho$$
, $\beta_2 = \alpha_L$, $\beta_3 = -\rho \alpha_L$, $\beta_4 = \alpha_K$, $\beta_5 = -\rho \alpha_K$, and $\eta_i^* = [1 - \rho] \eta_i$, and $\delta_t^* = \delta_t - \rho \, \delta_{t-1}$.

 Note that given the β parameters we can obtain the parameters ρ, α_L, and α_K. In fact, there are additional (over-identifying restrictions):

$$\begin{split} \rho &= \beta_1 = -\beta_3/\beta_2 = -\beta_5/\beta_4 \\ \alpha_L &= \beta_2 = -\beta_3/\beta_1 \\ \alpha_K &= \beta_4 = -\beta_5/\beta_1 \end{split}$$

• Now, under assumption FE-CO, in equation (2), the transitory shock a_{it} is not correlated with the inputs.

Victor Aguirregabiria ()

February 1st, 2021

22 / 62

Cochrane–Orcutt estimator

• Consider equation (4) in firm-specific means:

$$\overline{y}_i = \beta_1 \overline{y}_{i(-1)} + \beta_2 \overline{\ell}_i + \beta_3 \overline{\ell}_{i(-1)} + \beta_4 \overline{k}_i + \beta_5 \overline{k}_{i(-1)} + \eta_i^* + \overline{\delta}^* + \overline{a}_i$$

(5)

• And in deviations with respect to firm-specific means:

$$\begin{aligned} y_{it} - \overline{y}_i &= \beta_1 \left[y_{it-1} - \overline{y}_{i(-1)} \right] + \beta_2 \left[\ell_{it} - \overline{\ell}_i \right] + \beta_3 \left[\ell_{it-1} - \overline{\ell}_{i(-1)} \right] \\ &+ \beta_4 \left[k_{it} - \overline{k}_i \right] + \beta_5 \left[k_{it-1} - \overline{k}_{i(-1)} \right] \\ &+ \left(\delta_t^* - \overline{\delta}^* \right) + \left(a_{it} - \overline{a}_i \right) \end{aligned}$$

• The FE-Cocharne-Orcutt estimator is applying OLS to this equation.

Cochrane–Orcutt estimator: Large T condition

- **IMPORTANT NOTE:** The FE-Cochrane-Orcutt is consistent (asymp. unbiased) only when *T* is large, e.g., larger than 30 or 40 periods.
- Note that under condition FE-OC, we have that $(a_{it} \overline{a}_i)$ is not correlated with regressors $\left[\ell_{it} \overline{\ell}_i\right]$, $\left[\ell_{it-1} \overline{\ell}_{i(-1)}\right]$, $\left[k_{it} \overline{k}_i\right]$, and $\left[k_{it-1} \overline{k}_{i(-1)}\right]$.
- However, even under this condition, we have that $(a_{it} \overline{a}_i)$ is correlated with regressor $(y_{it-1} \overline{y}_{i(-1)})$.
- Note that y_{it-1} depends on $a_{i,t-1}$ and that $a_{i,t-1}$ is part of \overline{a}_i .
- This correlation goes to zero as T becomes large.

Arellano-Bond estimator

- Assumption FE-2 (or for that matter FE-CO) has two parts:
 - FE-2(a): u_{it} is not serially correlated.

- FE-2(b): u_{it} is not known to the firm when it decides the amounts of inputs.

- In most applications, the stronger of the two assumptions is FE-2(b).
- We now present a panel data estimator that relaxes assumption FE-2(b).

イロト 不得下 イヨト イヨト

Arellano-Bond estimator (2)

- We maintain assumptions FE-1, $\omega_{it} = \eta_i + \delta_t + u_{it}$, and FE-2(a), u_{it} is not serially correlated.
- Define the variables in first differences: $\Delta y_{it} = y_{it} y_{it-1}$; $\Delta \ell_{it} = \ell_{it} \ell_{it-1}$; etc.
- And consider the PF in first differences (equation at period t minus equation at period t 1):

$$\Delta y_{it} = \alpha_L \ \Delta \ell_{it} + \alpha_K \ \Delta k_{it} + \Delta \delta_t + \Delta u_{it}$$

- We have removed the term η_i from the error term, and we can control for the term $\Delta \delta_t$ by including time-dummies.
- But we still have the term Δu_{it} that is correlated with the regressors $\Delta \ell_{it}$ and Δk_{it} .

Victor Aguirregabiria ()

Arellano-Bond estimator (3)

$$\Delta y_{it} = \alpha_L \ \Delta \ell_{it} + \alpha_K \ \Delta k_{it} + \Delta \delta_t + \Delta u_{it}$$

 Consider the following general models for demand of capital and labor inputs:

(LD)
$$\ell_{it} = \beta_1^{LD} \ell_{i,t-1} + \beta_2^{LD} k_{i,t-1} + \beta_3^{LD} \omega_{it} + \beta_4^{LD} r_{it}$$

(KD) $k_{it} = \beta_1^{KD} \ell_{i,t-1} + \beta_2^{KD} k_{i,t-1} + \beta_3^{KD} \omega_{it} + \beta_4^{KD} r_{it}$

- This means that l_{it} and k_{it} depends on the current and the past histories of the transitory shocks: u_{it}, u_{it-1}, u_{i,t-2},;
- But not on future shocks: u_{it+1} , u_{it+1} ,

Victor Aguirregabiria ()

29 / 62

Arellano-Bond estimator (4)

$$\Delta y_{it} = \alpha_L \ \Delta \ell_{it} + \alpha_K \ \Delta k_{it} + \Delta \delta_t + \Delta u_{it}$$

- This implies that $\ell_{i,t-2}$ and $k_{i,t-2}$ are valid instruments in this equation.
- They are **Relevant**: $\Delta \ell_{it}$ and Δk_{it} are correlated with $\ell_{i,t-2}$ and $k_{i,t-2}$.
- They are not correlated with the error term:

$$\mathbb{E}\left[\ell_{it-2} \Delta u_{it}\right] = \mathbb{E}\left[\ell_{it-2} \ u_{it}\right] - \mathbb{E}\left[\ell_{it-2} \ u_{it-1}\right] = 0$$

(日) (同) (三) (三)

Arellano-Bond estimator (5)

• This idea implies many moment restrictions that can be used to estimate α_L , α_K , and $\Delta \delta_t$:

$$E(\ell_{i,t-j} \Delta u_{it}) = 0 \quad \text{for } t = 3, ..., T; \text{ and } j \le t-2$$
$$E(k_{i,t-j} \Delta u_{it}) = 0 \quad \text{for } t = 3, ..., T; \text{ and } j \le t-2$$
$$E(y_{i,t-j} \Delta u_{it}) = 0 \quad \text{for } t = 3, ..., T; \text{ and } j \le t-2$$

 The Arellano-Bond estimator exploits all these restrictions optimally: optimal weighting; optimal Generalized Method of Moments (GMM) estimator.

イロト イポト イヨト イヨト 二日

Arellano-Bond estimator: Implementation

- The command xtabond2 in Stata implements the Arellano-Bond estimator.
- It can be applied also to the model where u_{it} follows an autorregressive process.

5. System GMM estimator

(日) (同) (三) (三)

3

System GMM

- When labor and capital inputs are strongly correlated, the Arellano-Bond estimator suffers of a weak instruments problem: low correlation between instruments and endogenous variables, and imprecise estimates.
- Note that if ℓ_{it} and k_{it} follow "random walks" then $\Delta \ell_{it}$ and Δk_{it} are not serially correlated and therefore they are not correlated with the instruments ℓ_{it-2} and k_{it-2} .
- For these cases, Blundell-Bond derive additional restrictions that help to identify the PF.

イロト イポト イヨト イヨト 二日

Blundell and Bond (2001)

- They show that if the model is stationary, then Δℓ_{it} and Δk_{it} are not correlated with η_i.
- Therefore, in the PF in levels:

$$y_{it} = \alpha_L \ \ell_{it} + \alpha_K \ k_{it} + \delta_t + \eta_i + u_{it}$$

we have that $\Delta \ell_{it-1}$ and Δk_{it-1} are not correlated with error term $\eta_i + u_{it}$.

- This implies that $\Delta \ell_{it-1}$ and Δk_{it-1} are valid instruments in the equation in levels.
- **Relevant**. ℓ_{it} and k_{it} are correlated with $\Delta \ell_{it-1}$ and Δk_{it-1} (even when inputs follow random walks).
- No correlation with error: $E(\Delta \ell_{it-1} [\eta_i + u_{it}]) = E(\Delta k_{it-1} [\eta_i + u_{it}]) = 0$

35 / 62

Blundell and Bond (2001)

• The Blundell-Bond **System GMM estimator** combines these moment restrictions and Arellano-Bond moment restrictions in an optimal way to obtain an efficient estimator.

7. Control Function: Olley and Pakes estimator

Victor Aguirregabiria ()

Control Function Methods

- Olley & Pakes (1996; OP) and Levinsohn & Petrin (2003; LP) are control function methods.
- Instead of looking for instruments for K and L, we look for observable variables that can "control for" (or proxy) unobserved TFP.
- The control variables should come from a model of firm behavior.
- Note: Both OP and LP assume that labor is perfectly flexible input. This assumption is completely innocuous for their results. To emphasize this point, I present here versions of OP and LP that treat labor as a potentially dynamic input.

Olley and Pakes (OP)

• Consider the following model of simultaneous equations:

$$(PF) \quad y_{it} = \alpha_L \ \ell_{it} + \alpha_K \ k_{it} + \omega_{it} + e_{it}$$
$$(LD) \quad \ell_{it} = f_L (\ell_{i,t-1}, k_{it}, \omega_{it}, r_{it})$$
$$(ID) \quad i_{it} = f_K (\ell_{i,t-1}, k_{it}, \omega_{it}, r_{it})$$

(*LD*) & (*ID*): firms' optimal labor and investment given state variables ($\ell_{i,t-1}, k_{it}, \omega_{it}, r_{it}$); $r_{it} =$ input prices.

• OP consider the following assumptions:

$$\begin{array}{ll} (OP-1) & f_{\mathcal{K}}\left(\ell_{i,t-1},k_{it},\omega_{it},r_{it}\right) \text{ is invertible in } \omega_{it} \\ (OP-2) & \text{No cross-sectional variation in } r_{it} \colon r_{it}=r_t. \\ (OP-3) & \omega_{it} \text{ follows a first order Markov process.} \\ (OP-4) & k_{it} \text{ is decided at } t-1 \colon k_{it}=(1-\delta)k_{i,t-1}+i_{i,t-1} \end{array}$$

40 / 62

- OP method deals both with the simultaneity problem and with the selection problem due to endogenous exit.
- It doesn't deal with potential measurement error in inputs.
- OP method proceeds in two stages.
- First stage: estimates α_L [Assumptions (OP-1) and (OP-2) are key]; and the second stage estimates α_K [Assumptions (OP-3) and (OP-4) are key].

イロト 人間ト イヨト イヨト

Olley and Pakes

First Stage

 Assumptions (OP-1) and (OP-2) imply that the investment equation is invertible in ω_{it}:

$$\omega_{it} = f_{K}^{-1}(\ell_{i,t-1}, k_{it}, i_{it}, r_t)$$

• Solving this equation in the PF we have:

$$y_{it} = \alpha_L \ \ell_{it} + \alpha_K \ k_{it} + f_K^{-1}(\ell_{i,t-1}, k_{it}, i_{it}, r_t) + e_{it}$$

$$= \alpha_L \ell_{it} + \phi_t(\ell_{i,t-1}, k_{it}, i_{it}) + e_{it}$$

- This is a **partially linear model**. Parameter α_L and functions $\phi_1(.)$, ..., $\phi_T(.)$ can be estimated using **semiparametric methods**.
- A possible method is Robinson's method (1988). OP use an n-th order polynomial to approximate the ϕ_t functions.

Victor Aguirregabiria ()

Olley and Pakes First Stage

- This first stage is a "Control Function" method: instead of instrumenting the endogenous regressors, we include additional regressors that capture the endogenous part of the error term.
- We are controlling for endogeneity by including $(\ell_{i,t-1}, k_{it}, i_{it})$ as "proxies" of ω_{it} .
- Key assumptions for the identification of α_L :

(a) Invertibility of $f_{K}(\ell_{i,t-1}, k_{it}, \omega_{it}, r_{t})$ w.r.t ω_{it} .

(b) $r_{it} = r_t$, i.e., no cross-sectional variability in unobservables, other than ω_{it} , affecting investment.

(c) Given $(\ell_{i,t-1}, k_{it}, i_{it}, r_t)$, labor ℓ_{it} still has sample variability.

▲□▶ ▲□▶ ▲□▶ ▲□▶ □ のの⊙

Olley and Pakes First Stage

• Example (with parametric linear investment func.):

$$\begin{array}{ll} (PF) \quad y_{it} = \alpha_L \ \ell_{it} + \alpha_K \ k_{it} + \omega_{it} + e_{it} \\ \\ (\textit{Inverse ID}) \quad \omega_{it} = \gamma_1 \ i_{it} + \gamma_2 \ \ell_{i,t-1} + \gamma_3 \ k_{it} + \gamma_4 \ r_{it} \end{array}$$

Then.

$$y_{it} = \alpha_L \ \ell_{it} + (\alpha_K + \gamma_3) \ k_{it} + \gamma_1 \ i_{it} + \gamma_2 \ \ell_{i,t-1} + (\gamma_4 r_{it} + e_{it})$$

- Note that ℓ_{it} is correlated with r_{it} . Therefore, we need $r_{it} = r_t$ and include time dummies to control for r_t in order to have consistency of the OLS estimator in this regression.
- Note also that to identify ℓ_{it} with enough precision we need not high collinearity between this variable and $(k_{it}, i_{it}, \ell_{i,t-1})$.

Victor Aguirregabiria ()

Olley and Pakes Second Stage

• **Estimation of** $\alpha_{\mathcal{K}}$. It is based on the other two assumptions:

$$(OP-3)$$
 ω_{it} follows a first order Markov process.
 $(OP-4)$ k_{it} is decided at $t-1$: $k_{it} = (1-\delta)k_{i,t-1} + i_{i,t-1}$

• Since ω_{it} is first order Markov, we can write:

$$\omega_{it} = E[\omega_{it} \mid \omega_{i,t-1}] + \xi_{it} = h(\omega_{i,t-1}) + \xi_{it}$$

where ξ_{it} is an innovation which is mean independent of any information at t - 1 or before. And h(.) is some unknown function.

• ϕ_{it} is identified from 1st step; and $\phi_{it} = \alpha_K k_{it} + \omega_{it}$. Then,

$$\phi_{it} = \alpha_{K} k_{it} + h \left(\phi_{i,t-1} - \alpha_{K} k_{i,t-1} \right) + \xi_{it}$$

45 / 62

Olley and Pakes Second Stage

 We estimate h(.) and α_K by applying recursively the same type of semiparametric method as in the first stage of OP.

$$\phi_{it} = \alpha_{K} k_{it} + h \left(\phi_{i,t-1} - \alpha_{K} k_{i,t-1} \right) + \xi_{it}$$

• Suppose that we consider a quadratic function for h(.): i.e., $h(\omega) = \pi_1 \omega + \pi_2 \omega^2$. Then:

$$\phi_{it} = \alpha_{K} \, k_{it} + \pi_1 \left(\phi_{i,t-1} - \alpha_{K} \, k_{i,t-1} \right) + \pi_2 \left(\phi_{i,t-1} - \alpha_{K} \, k_{i,t-1} \right)^2 + \xi_{it}$$

• It is clear that α_K , π_1 and π_2 are identified in this equation.

Victor Aguirregabiria ()

イロト イポト イヨト イヨト 二日

Olley and Pakes Second Stage

• Time-to build is a key assumption for the consistency of this method. If investment at period *t* is productive, then the equation becomes:

$$\phi_{it} = \alpha_{K} \, k_{i,t+1} + h \left(\phi_{i,t-1} - \alpha_{K} \, k_{it} \right) + \xi_{it}$$

 k_{i,t+1} depends on investment at period t and therefore it is correlated with the innovation ξ_{it}.

- US Telecom. equipment industry: 1974-1987.
- Technological change and deregulation.
 - Elimination of barriers to entry;
 - Antitrust decisions against AT&T: The Consent Decree (implemented in 1984) -> divestiture of AT&T.
 - Substantial entry/exit of plants.
- Data: US Census of manufacturers.

8. Control Function: Levinsohn-Petrin estimator

Image: Image:

Levinshon & Petrin (2003)

• The main difference with OP method is that LP use the demand function for intermediate inputs instead of the investment equation to invert out unobserved productivity.

• Two main motivations:

- Investment can be responsive to more persistent shocks in TFP; materials is responsive to every shock in TFP.

- In some datasets **Zero Investment** accounts for a large fraction of the data. At $i_{it} = 0$ (corner solution / extensive margin) there is not invertibility between i_{it} and ω_{it} . Problems: loss of efficiency; missing estimates of TFP for many observations.

イロッ イボッ イヨッ イヨッ 三日

Levinshon & Petrin (2003)

• They consider a Cobb-Douglas production function in terms of labor, capital, and intermediate inputs (materials):

$$y_{it} = \alpha_L \ \ell_{it} + \alpha_K \ k_{it} + \alpha_M \ m_{it} + \omega_{it} + e_{it}$$

• Investment equation is replaced with demand for materials:

$$m_{it} = f_M\left(\ell_{i,t-1}, k_{it}, \omega_{it}, r_{it}\right)$$

- Assumption LP-1: $f_M(\ell_{i,t-1}, k_{it}, \omega_{it}, r_{it})$ is invertible in ω_{it} .
- They maintain OP-2 [No other unobservables; $r_{it} = r_t$], OP-3 [Markov TFP], and OP-4 [Time-to-build].

54 / 62

イロト 不得 トイヨト イヨト 二日

Levinshon & Petrin: First Step

Least squares estimation of parameter α_L and the nonparametric functions {φ_t(.): t = 1, 2, ..., T} in regression equation:

$$y_{it} = \alpha_L \ \ell_{it} + \phi_t(\ell_{i,t-1}, k_{it}, m_{it}) + e_{it}$$

• $\phi_t(\ell_{i,t-1}, k_{it}, m_{it}) = \alpha_K k_{it} + \alpha_M m_{it} + f_M^{-1}(\ell_{i,t-1}, k_{it}, m_{it}, r_t)$ and f_M^{-1} is the inverse function of f_M with respect to ω_{it} .

Levinshon & Petrin: Second Step

- The second step is also similar to OP's second step but in the model with the intermediate input.
- ϕ_{it} is estimated in 1st step; and $\phi_{it} = \alpha_K \ k_{it} + \alpha_M \ m_{it} + \omega_{it}$. Then,

$$\phi_{it} = \alpha_{K} k_{it} + \alpha_{M} m_{it} + h \left(\phi_{i,t-1} - \alpha_{K} k_{i,t-1} - \alpha_{M} m_{i,t-1} \right) + \xi_{it}$$

- Important difference with OP: In this second step $E(m_{it} \xi_{it}) \neq 0$, i.e., materials m_{it} is endogenous.
- LP propose two approaches:

- **"unrestricted method"**: instrument m_{it} with its lagged values [see GNR (2013) criticism];

- "restricted method": under static input, price-taking: $\alpha_M =$ Cost of materials/Revenue.

• Plant-level data from 8 different Chilean manufacturing industries: 1979-1985 [Pinochet period].

First order conditions for flexible inputs

• Suppose that labor is a perfectly flexible input and the firm is a price-taker in output and labor markets. Then, F.O.C. imply:

$$\mathsf{P}_{it} \; rac{\partial Y_{it}}{\partial L_{it}} = W_{it}$$

• For the Cobb-Douglas PF, this condition becomes:

$$\alpha_L = \frac{W_{it} \ L_{it}}{P_{it} \ Y_{it}}$$

i.e., α_L is identified by the wage bill-to-revenue ratio.

• In fact, this condition rejects this simple version of the model. Substantial sample variation in $\frac{W_{it} L_{it}}{P_{it} Y_{it}}$. Either $\alpha_{L,it}$, or unobserved heterogeneity in cost of labor, or other assumptions do not hold.
