ECO 310: Empirical Industrial Organization

Lecture 6: Demand Systems:
Discrete Choice Models

Victor Aguirregabiria (University of Toronto)

October 13, 2022

Outline on today's lecture

- 1. Limitations of demand systems from consumer preferences in product space
- 2. Discrete choice models of consumer demand & and consumer preferences in characteristics space
 - 2.1. General Model
 - 2.2. Standard Logit Model
 - 2.3. Nested Logit Model [Next week]
 - 2.4. Model with heterogeneous coefficients [Next week]

1. Limitations of Demand Systems in Product Space:

3 / 30

Limitations: Demand systems product space

- Demand models in 'product space' have several practical limitations in IO applications.
 - 1. Positive consumption of all products.
 - 2. "Too many" parameters.
 - 3. Finding instruments for prices.
 - 4. Problems to predict demand of new varieties.

[1] Positive consumption of all products

- The model assumes the marginal conditions of optimality hold for every product.
- This means that $q_j > 0$ for every product j.
- This condition is very unrealistic when we consider the demand of differentiated products within a product category, e.g., the demand of automobiles.
- In this context, a consumer buys only one unit of a single variety (e.g., one Toyota Corola) or of a few varieties (e.g., one Toyota Corola, and one KIA Sorento minivan).
- To account for this type of consumer decisions, we need to model the consumer problem as a discrete choice model.

[2] Too many parameters

$$w_{jt} = \beta_j^{(0)} + \beta_j^{(y)} \ln\left(rac{y_t}{P_t}
ight) + \sum\limits_{k \in J_g} \beta_{jk}^{(p)} \ln(p_{kt}) + \xi_{jt}$$

- The number of parameters increases quadratically with the number of products J.
- It is not possible to estimate demand systems for differentiated products with many varieties.
- For instance, demand system for car models. With J=100, the #parameters = 5, 250.
- Even with the restrictions of multi-stage budgeting and multiple groups and nests, the number of parameters is large.

◆ロト ◆問 ト ◆ 恵 ト ◆ 恵 ・ り へ ○

[3] Finding instruments for prices

$$w_{jt} = eta_j^{(0)} + eta_j^{(y)} \; \ln\left(rac{y_t}{P_t}
ight) + \sum\limits_{k \in J_g} eta_{jk}^{(p)} \; \ln(p_{kt}) + \xi_{jt}$$

- In the AIDS model, for the equation of a product, we have as many endogenous regressors (prices) as products.
- If we deal with the endogeneity of prices using Instrumental Variables, we need as many instruments as products, J.
- The ideal case is when we have information on production costs for each individual good. However, that information is very rarely available.

[4] Problems to predict demand of new varieties

$$w_{jt} = eta_j^{(0)} + eta_j^{(y)} \; \ln\left(rac{y_t}{P_t}
ight) + \sum\limits_{k \in J_g} eta_{jk}^{(p)} \; \ln(
ho_{kt}) + \xi_{jt}$$

- A problem that has received substantial attention in IO is the prediction of the demand of a new product.
- In a demand system in product space, estimating the demand of a new good requires estimates of the parameters associated with that good. If the new product is J+1: $\{\beta_{J+1}^{(0)},\,\beta_{J+1}^{(y)},\,\beta_{J+1,j}^{(p)}$: for $j=1,2,...,J+1\}$.
- This makes it impossible to make predictions on demand of a product that has not been introduced yet in any market.
- It also limits the applicability of this model in cases where the new product has been introduced very recently or in very few markets, because we may not have enough data to estimate these parameters.

2. Discrete choice models of consumer demand

9 / 30

Discrete choice demand models: Basic Assumptions

- The basic assumptions are:
 - (1) A product, say a laptop computer, can be described in terms of a bundle of physical characteristics: e.g., CPU speed, memory, screen size, etc. These characteristics determine a product.
 - (2) Consumers have preferences on characteristics of products, not on the products per se.
 - (3) A product category (e.g., laptops) has J different products and each consumer buys at most one variety of the product per period. This implies that the J products are substitutes with each other.

Model: Products

- We index varieties by $j \in \{1, 2, ..., J\}$.
- We can distinguish two sets of product characteristics.
- Characteristics observable to the researcher:

$$\mathbf{X}_{j} \equiv (X_{1j}, X_{2j}, ..., X_{Kj})$$

 X_{kj} represents the "amount" of attribute k in product j.

- Example (Laptops): $X_{1j} = \text{CPU}$ speed; $X_{2j} = \text{RAM}$ memory; $X_{3j} = \text{hard disk memory}$; $X_{4j} = \text{weight}$; $X_{5j} = \text{screen size}$; $X_{6j} = \text{dummy}$ 'Intel inside'; etc.
- Other characteristics are not observable to the researcher but they are known and valued by consumers. We use ξ_j to represent the unobservable (to the researcher) characteristics of product j.

4 U P 4 DP P 4 E P 4 E P E 9) 4

Model: Consumer Preferences.

• The utility of household h if purchases product j is:

$$U_{hj} = u(c_h) + \mathbf{X}_j \ \beta_h + \xi_j + \varepsilon_{hj}$$

- c_h is consumption of the "outside good" and $u(c_h)$ is the corresponding utility.
- \mathbf{X}_j $\boldsymbol{\beta}_h = \boldsymbol{\beta}_{1h} X_{1j} + \boldsymbol{\beta}_{2h} X_{2j} + ... + \boldsymbol{\beta}_{Kh} X_{Kj}$ is the utility from the observable characteristics.
- Coefficient β_{kh} represents the marginal utility of this product characteristic (e.g., RAM memory) for consumer h.
- ullet ξ_j is utility from unobservable characteristics, the same for all consumers.
- ε_{hj} is an idiosyncratic taste of consumer h for product j that is unobservable to the researcher.

Model: Budget constraint

• Budget constraint of consumer h, with income y_h , if buys product j:

$$c_h + p_j \leq y_h$$

To represent no purchase of any of the J products we use j=0, with $p_0=0$, $\mathbf{X}_j=0$, and $\xi_j=0$.

• The utility of purchasing product j, after taking into account the budget constraints $(c_h = y_h - p_j)$ becomes:

$$U_{hj} = u(y_h - p_j) + \mathbf{X}_j \ \beta_h + \xi_j + \varepsilon_{hj}$$

4□ > 4□ > 4 = > 4 = > = 9 < 0</p>

Model: Consumer decision problem

- A consumer chooses the alternative $j \in \{0, 1, ..., J\}$ that maximizes her utility U_{hj}
- Consumer h chooses product j if and only if:

$$U_{hj} > U_{hi}$$
 for any $i \neq j$

Or equivalently, if and only if:

$$u(y_h - p_j) + \mathbf{X}_j \ \beta_h + \xi_j + \varepsilon_{hj} > u(y_h - p_i) + \mathbf{X}_i \ \beta_h + \xi_i + \varepsilon_{hi}$$
 for any $i \neq j$

4□ > 4□ > 4 = > 4 = > = 9 < 0</p>

Model: Individual consumer (unit) demands

- Let q_{hj} represent the quantity of product j demanded by consumer h.
- In this model, q_{hj} is either 0 or 1: $q_{hj} \in \{0, 1\}$.
- The demand is:

$$q_{hj} = \left\{egin{array}{ll} 1 & ext{if} & U_{hj} > U_{hi} & ext{for any } i
eq j \ & & & & & & & & & & \end{array}
ight.$$

with
$$U_{hj} = u(y_h - p_j) + \mathbf{X}_j \beta_h + \xi_j + \varepsilon_{hj}$$
.

• These unit demands depend on income, all the product prices, and all the product characteristics \mathbf{X}_j and ξ_j .

→ロト → □ ト → 重 ト → 重 ・ りへで

Model: Aggregate demand / Market shares

• Let s_j be the proportion of consumers who purchase product j.

$$s_j = rac{\sum_{h=1}^{H} q_{hj}}{H} = \Pr\left(q_{hj} = 1\right)$$

• We describe s_j as the **market share of product** j. According to model:

$$s_j = \Pr\left(U_{hj} > U_{hi} \quad \text{for any } i \neq j\right)$$

$$= \Pr\left(\begin{array}{c} u(y_h - p_j) + \mathbf{X}_j \beta_h + \xi_j + \varepsilon_{hj} \\ > u(y_h - p_i) + \mathbf{X}_i \beta_h + \xi_i + \varepsilon_{hi} \\ \text{for any } i \neq j \end{array}\right)$$

• This probability (market share) results from integrating the individual demand q_{hj} over the distribution of $(\beta_h, \varepsilon_h, y_h)$.

Victor Aguirregabiria () Demand October 13, 2022 16 / 30

Different types of discrete choice models

- The particular type of discrete choice model depends on three types of assumptions.
- [1] The specification of the "utility of money" u(.), e.g., linear or logarithmic function.
- [2] The probability distribution of the variables ε_{hj} , e.g., Logit or Probit.
- [3] The assumptions on the coefficients β_h , e.g., constant $(\beta_h = \beta$ for every h) or heterogeneous coefficients.

⟨□⟩ ⟨□⟩ ⟨□⟩ ⟨□⟩ ⟨□⟩ □ ⟨○⟩

- We will study three examples of discrete choice demand models that have received a lot of attention in empirical applications.
- [1] Standard Logit model Linear u(.); $\varepsilon_{hj}\sim$ i.i.d. Extreme Value; and $\beta_h=\beta$.
- [2] Nested Logit model Linear u(.); $\varepsilon_{hj} \sim$ Sum of two i.i.d. Extreme Values; and $\beta_h = \beta$.
- [3] Random coefficients Logit model u(.) may be nonlinear ; $\varepsilon_{hj} \sim \text{i.i.d.}$ Extreme Values; and β_h are heterogeneous across individuals according to some distribution.

2.1. Standard Logit Model

19 / 30

Extreme value distribution: Some properties

• We say that a random variable ε has an Extreme Value type 1 distribution (or Gumbel distribution) iff its Cumulative Distribution Function is:

$$F(\varepsilon) = \exp\{-\epsilon\}\}$$

- ε has support $(-\infty, +\infty)$. The density function is bell shaped but asymmetric.
- Suppose that the variables ε_0 , ε_1 , ..., ε_J are all Extreme Value and independently distributed. These variables satisfy two properties that are useful for discrete choice models.

◆□▶ ◆□▶ ◆□▶ ◆■▶ ■ りへで

Extreme value distribution: Some properties [2]

• For any vector of constants $(\delta_0, \delta_1, ..., \delta_J)$, we have that:

$$\Pr(\delta_j + \varepsilon_j > \delta_i + \varepsilon_i \text{ for any } i \neq j) = \frac{\exp\{\delta_j\}}{\sum_{i=0}^{J} \exp\{\delta_i\}}$$

And:

$$\mathbb{E}\left(\max_{j\in\{0,1,...,J\}}\left[\delta_j+\varepsilon_j\right]\right)=\ln\left(\sum_{j=0}^{J}\exp\left\{\delta_j\right\}\right)$$

4□ > 4□ > 4 = > 4 = > = 9 < 0</p>

21 / 30

Standard Logit Demand Model

• Suppose that $u(c) = \alpha \ c$ [Linear]; $\beta_h = \beta$ for every h; and all the ε_j 's are i.i.d. Extreme Value Type 1. Then,

$$U_{hj} = -\alpha \ p_j + \mathbf{X}_j \ \beta + \xi_j + \varepsilon_{hj}$$

- If we define $\delta_j \equiv -\alpha \ p_j + \mathbf{X}_j \ \beta + \xi_j$, then δ_j represents the average utility of purchasing product j for every consumer in the market.
- ullet The only idiosyncratic component of utility is $arepsilon_{hj}$.
- The model implies that the market shares are:

$$s_{j} = \frac{\exp\left\{\delta_{j}\right\}}{1 + \sum\limits_{i=1}^{J} \exp\left\{\delta_{i}\right\}} = \frac{\exp\left\{-\alpha \ p_{j} + \mathbf{X}_{j} \ \beta + \xi_{j}\right\}}{1 + \sum\limits_{i=1}^{J} \exp\left\{-\alpha \ p_{i} + \mathbf{X}_{i} \ \beta + \xi_{i}\right\}}$$

because $\delta_0 = -\alpha \ p_0 + \mathbf{X}_0 \ \beta + \xi_0 = 0$.

◆ロト ◆個ト ◆差ト ◆差ト 差 めらゆ

Standard Logit Demand Parameters

When the indirect utility has this form,

$$U_{hj} = -\alpha p_j + \beta_1 X_{1j} + ... + \beta_K X_{Kj} + \xi_j + \varepsilon_{hj}$$

we have that the parameters β and α have a very clear economic interpretation.

- α is the marginal utility of income (or marginal utility of money), and it is measure in "utils" per dollar.
- β_k is the marginal utility of attribute k, and it is measure in "utils" per unit of this attribute.
- Therefore, $\frac{\beta_k}{\alpha} = \frac{\text{utils } / \text{ unit of } k}{\text{utils } / \$} = \frac{\$}{\text{unit of } k}$ is the marginal value of attribute k measured in dollars per unit of the attribute.

4 L P 4 BP P 4 E P 4 E P 4 E P 9 C C

Standard Logit Demand: Elasticities

• In the logit model, $s_j = \exp\{\delta_j\} / [1 + \sum_{i=1}^J \exp\{\delta_i\}]$, implies that (prove it):

$$rac{ds_j}{d\delta_j} = s_j \ (1-s_j) \quad ext{and} \quad rac{ds_j}{d\delta_i} = -s_j \ s_i \quad ext{for} \ i
eq j$$

Therefore, the own price elasticities are:

$$\frac{ds_j}{dp_j}\frac{p_j}{s_j} = \left[\frac{ds_j}{d\delta_j}\frac{d\delta_j}{dp_j}\right]\frac{p_j}{s_j} = s_j \ (1-s_j) \ [-\alpha] \ \frac{p_j}{s_j} = -\alpha \ (1-s_j) \ p_j$$

And the cross price elasticities are:

$$\frac{ds_j}{dp_i}\frac{p_i}{s_j} = \left[\frac{ds_j}{d\delta_i}\frac{d\delta_i}{dp_i}\right]\frac{p_i}{s_j} = -s_j \ s_i \ [-\alpha] \ \frac{p_i}{s_j} = \alpha \ s_i \ p_i$$

Standard Logit Demand Model: Estimation

• According to the model, for any product j = 1, 2, ..., J:

$$\frac{s_j}{s_0} = \exp\left\{-\alpha \ p_j + \mathbf{X}_j \ \beta + \xi_j\right\}$$

such that:

$$\ln(s_j) - \ln(s_0) = -\alpha \ p_j + \mathbf{X}_j \ \beta + \xi_j$$

- This is a linear regression model with regressors (p_j, \mathbf{X}_j) , parameters (α, β) , and error term ξ_i .
- If the number of product J is large enough relative to the number of observable product characteristics K, then we can estimate the parameters of this model using a cross-section of consumers (one market).

Logit Demand Model: Some advantages

- Let's revisit the limitations of the traditional demand systems and see that the Logit model overcomes these limitations.
- [1] Positive consumption of all products. As a discrete choice model, the logit does not have this unrealistic prediction.
- [2] "Too many" parameters. The number of parameters (α, β) is K+1 that does not increase with the number of products J. Having many products (large J) is a blessing for this model (more degrees of freedom, more precise estimates).
- [3] Finding instruments for prices. There is only one endogenous regressor in the model. We need only one instrument.
- [4] Predict demand of new varieties. Given (α, β) , we can predict the demand of any hypothetical product with characteristics (p^*, \mathbf{X}^*) . [More on this below].

Victor Aguirregabiria () Demand October 13, 2022 26 / 30

Estimation: Endogeneity

We have the regression model:

$$\ln{(s_j)} - \ln{(s_0)} = \beta^{(p)}~p_j + \mathbf{X}_j~\beta + \xi_j$$
 with $\beta^{(p)} = -\alpha$.

• **Endogeneity of prices:** Products with better (higher) unobserved quality ξ_i tend to have higher prices:

$$cov(p_j, \xi_i) > 0$$

We will see this formally in the topic of models of price competition.

 This endogeneity problem implies that the OLS estimate of the parameter associated to price is upward bias:

$$\widehat{eta}^{(p)}
ightarrow eta^{(p)} + rac{cov(p_j, \xi_j)}{var(p_j)}$$

ullet We could even get $\widehat{eta}^{(p)}$ is positive or not significantly different to zero.

IV Estimation: BLP instruments

- Berry, Levinsohn, & Pakes (1996) proposed the following instrument for price in discrete choice models: BLP instruments.
- Suppose that price is the only endogenous regressor such that $\mathbb{E}\left(\mathbf{X}_{j} \ \xi_{j}\right)=0.$
- Firms' price competition imply that the price of a product depends on its product characteristics $(\mathbf{X}_j \ \xi_j)$, but also on the characteristics of the competing products, $(\mathbf{X}_i, \ \xi_i : i \neq j)$.
- Intuitively, if the other products have characteristics very similar to j, competition is more intense and p_j will be small. But if product j has very different characteristics to the other products, firm j can enjoy some market power from product differentiation and p_j can be larger.
- The idea is using $(\mathbf{X}_i : i \neq j)$ as an instrument for p_j .

28 / 30

[2]

IV Estimation: BLP instruments

- Suppose that we use the vector of instruments $\mathbf{Z}_j = (Z_{1j}, Z_{2j},, Z_{Kj})$ where for any product characteristic k, $Z_{kj} = \frac{\sum_{i \neq j} X_{ki}}{J-1}$.
- We could consider other functions of $(\mathbf{X}_i: i \neq j)$ as instruments, such as the average distance, $Z_{kj} = \frac{\sum_{i \neq j} |X_{ki} X_{kj}|}{J-1}$.
- \mathbf{Z}_{j} is a vector of valid instruments for p_{j} in the regression equation $\ln(s_{j}) \ln(s_{0}) = \beta^{(p)} p_{j} + \mathbf{X}_{j} \beta + \xi_{j}$ because:
 - [1] They are not regressors in this regression function (the utility of product j depends only on characteristics of product j);
 - [2] They are not correlated with the error term ξ_j (by assumption);
 - [3] They are correlated with p_j (testable restriction).

◆□▶◆□▶◆豆▶◆豆▶ 豆 りQ@

Logit Demand Model: Some limitations

 The standard Logit model imposes some strong restrictions on price elasticities.

$$\frac{ds_j}{dp_j} \frac{p_j}{s_j} = -\alpha \ (1 - s_j) \ p_j$$
 and $\frac{ds_j}{dp_i} \frac{p_i}{s_j} = \alpha \ s_i \ p_i$

- And increase in the price of product i (e.g., a luxury car) implies the same increase in the demand of product j (other luxury car) as in the demand of product b (a very low quality car).
- We can introduce two extensions in the model that relax this restriction:
 - [A] Consumer heterogeneous coefficients β_h
 - [B] Nested Logit model for ε_h

4 D > 4 D > 4 E > 4 E > E 990
